TRANSLATE THE FOLLOWING TEXT:

New research published this week in The Lancet medical journal found that those taking both aspirin and ibuprofen were twice as likely to die during the study period as those who were taking aspirin alone or with other types of common pain relievers. Scientists believe ibuprofen clogs a channel inside a clotting protein that aspirin acts on. Aspirin gets stuck behind the ibuprofen and cannot get to where it is supposed to go to thin the blood. Aspirin is considered the most important medicine for heart disease. Nearly all heart patients take it every day because it prevents the clots that cause heart attacks and strokes. Ibuprofen, which is in Motrin and Advil among other brands, is widely used for arthritis and other aches and pains. Scientists at the Medicines Monitoring Unit of Britain's Medical Research Council checked the medical records of 7,107 heart patients who had been discharged from hospitals with aspirin prescriptions and had survived at least one month after leaving the hospital. They were divided into four groups according to their prescriptions. The first group included those on aspirin alone. The second were given aspirin and ibuprofen and the third group had aspirin with another pain killer, diclofenac. Ibuprofen and diclofenac both belong to a widely used class of pain relievers known as nonsteroidal anti-inflammatory drugs, or NSAIDs. The last group included those taking aspirin with other NSAID, such as acetaminophen, which is in Tylenol. The researchers found that those taking ibuprofen were almost twice as likely as those taking aspirin alone to die. That meant that for every 1,000 patients treated, there were 12 extra deaths a year when ibuprofen was taken with aspirin.
